AttySpace Tutorial: Getting Started

Ben "Damnal" Cotton (Damnal@ATS) 12/21/02 See Change Log at the end of the document

Note: This tutorial assumes you are logged in as One on Mordak and Yarb's stock database or my own stock database. Unfortunately for many of you, my stock database, which contained fixes to many of the glitches in the vanilla one is not compatible with newer compiles. Also because of certain features kludged into my server, I won't be providing another copy of mine, since odds are you do not have my hardcode patches.

If you're completely new to AttySpace (if you've never used it on ATS), then I suggest you read Shaard's Beginner's Guide, which is available at http://www.trekmush.org/files/sguide.txt, otherwise enjoy the tutorial.

If you have never, ever used soft or hardcode, do not attempt to start a public MUSH. Learn to softcode and then move onto bigger and better things.

Table of Contents:

- 2 Adding Rooms to Ships.
- 3 Creating Bases and Planets
- 4 Fun with SDB
- 5 Class Creation
- 6 Questions and Answers
- 98 Contact Information
- 99 Change Log

First we'll cover the basic creation of a ship, as creating classes is a little difficult and someone else is writing a tutorial about it. If you've installed Yarb's @space/makeship command on #10 you should skip this next part of the tutorial as this part is about the manual creation of a ship.

1 – Creating your first ship

The first step is to create the object, which will represent your ship. This object will hold all the fun stuff like the coordinates of your ship, it's allocations, it's damage etc. For this tutorial we'll create one called SS Shuttle. This will be our ship, or at least a near resemblance of one.

Next we have to decide what class our ship should be, a plain old shuttle looks good, so @parent SS Shuttle to #66. We now know what class our ship is.

The next step is to add the zone lock to our ship, the standard one I've seen used in the database is: iswiz/1 this uses the iswiz lock that is on #30, the master space object.

Now that this is done, create the bridge for your ship by @dig'ing it. @chzone the room to your ship object.

Next we need a few consoles, so lets create a few. @create 3 objects called Console 1, Console 2, and Console 3, respectively. Drop all three objects and paste the following code segment into your telnet window.

```
@dolist remove(lcon(here),%!)=&NAME ##=s(name(##))
@dolist remove(lcon(here),%!)=@set ##=wizard
@dolist remove(lcon(here),%!)=@set ##=monitor
@dolist remove(lcon(here),%!)=&SHIP ##=s(zone(here))
@dolist remove(lcon(here),%!)=@parent ##=#21
@dolist remove(lcon(here),%!)=&MODES ##=command communications
engineering helm inactive monitor navigation off operations science
security tactical transporter weapons damage fighter
```

Next we need to determine the next available sdb#. To do this we'll call sdb(e), which will give us the next available number. Now we'll add the sdb attribute to our ship object/zone with a value of the number we were just given. Now we have to make sure the consoles have the proper data on them. We'll do this by pasting the following line into our telnet session.

```
@dolist remove(lcon(here),%!)=&SDB ##=s(get(zone(here)/sdb))
```

There, now our consoles are set to work with our ship, and our ship is almost set to work in space. We just need to do a few more little things.

First we have to load our ship into the space database, otherwise we can't fly. Now, a very critical step, set the ship object (in my example #212) SHIP-OBJECT by typing: @set #212=SHIP-OBJECT. So now we'll execute the sdb() function with the following parameters, (substitute the number of your ship for the number in this code): sdb(read, #212)

If all goes well, you'll be given a nice return of 1 for your trouble, if you somehow got 0, there's a bug in your ship object, (most likely it's not parented properly). If you got a 1 however man a console and try to start your ship.

Uh oh... no fuel, that could be a problem if we want to go anywhere. Well we can remedy this problem very easily, just paste in the following code. Substitute the sdb number of your ship for the 7 in this code.

```
Th sdb(put,7,320000000,fuel,anti)
Th sdb(put,7,640000000,fuel,deut)
```

There, we now have a fully functional Shuttle in space. It should only take you about 15 hours to get to where the ships that Mordak and Yarb included are. ©

2 – Adding Rooms to your Ship

Adding a new room to your ship that will display things such as the destruction messages is quite simple. First @dig the room and link it to the first, if you want to. @chzone the room to the ship you want it to be part of. Next you have to add the number of the room you just created into the ROOMS attrib on ship obj. The attrib is a space delimited list so you should have any troubles. Enjoy the multiple rooms on your ship.

3 – Creating Planets and Bases

Wow, creating planets and bases is really easy, to be exact it's the same as creating a ship, just with different parents. The only real different I see is that you don't have to fuel planets, though, if you create a planet class with sensors or the like, I'd recommend giving them some.

4 – Fun stuff with SDB()

SDB() is the function that give AttySpace life, it handles everything, from putting your ship in space to changing it's allocs etc. As you saw earlier in this tutorial, sdb is used to initialize your ship.

A lot of people seem to want to know how to change the coordinates of their ship so I'll use this section (for now) to show how this is done.

```
th sdb(put, <sdb#>, [pc2su(100)], coords, x)
```

That line would move the x value of your ship to 100. I think you can figure out the rest easily.

Using sdb() you can also refuel ships, gate anomalies and essentially everything you can do with the consoles.

You can take a look at the sdb() reference table at the end of the document if you need to find specific sdb() commands.

5 – Class Creation (and some other really tedious stuff)

Well, today's lesson is about class creation. Class creation takes a little bit of thought, and a whole lot of typing. You have to think about how big a ship you want, if you want weapons on the ship, and if so, where they should face. How much power should the ship have? How strong should the shields be? These are all questions you'll ask yourself when designing your class. My first suggestion is to write down on paper most of the things you want to remember about the class you're going to create. Mordak's description of each attribute is a must when designing your ship, as it's essentially your template. There are a few formulae that you may want to remember when designing your class. The important ones relate to warp speeds.

The first determines **p** which, I'll say, stands for power for lack of a better term.

 $\mathbf{p} = (0.99 * \text{total MW produced by main}) + (0.01 * \text{total power * power % alloc'ed to move})$ The other important variable, \mathbf{a} , is the 5th variable in the movement list. This variable is very important in a lot of the other calculations too.

Warp Speed = sqrt(10.0 * p / a)

On a side note, when the ship is travelling with a cloaking device active, \mathbf{p} is multiplied by 0.75. If the shields are active, it is multiplied by 0.75 for each shield that is up. IE, All four shields are up and \mathbf{p} has a value of oh 10. The final \mathbf{p} would be: 3.16. Cloaking changes the speed in the same way.

Impulse speeds are calculated in almost the same way, however instead of the total MW produced by the main, it is based on the MW of the aux. However impulse isn't affected by the shields or cloak.

Maximum fuel is fun. Full antimatter is determined by multiplying your movement ratio (5th variable in the movement list) by the ship's light year range (the final variable in the technology list) multiplied by 640000000. Deuterium is based on the same formula but substituting 320000000 instead of 640000000.

With this information and Yarb's crib sheet you should be able to create a half decent class within an hour or so.

Here is our example ship class (do not use this on a public MUSH without my permission). I call it the Avalon class Raider. It's a small ship, a little larger than some of the fighters that come in the stockdb, but unlike the fighters has cargo space. It also includes a cloaking device, whose power usage is balanced the same way as that of the D'deridex III in the stockdb. The normal warp speed for this ship is 15.31 and the impulse speed is 98.

@create Avalon
&CLASS Avalon=Avalon

This part should be fairly self-explanatory.

&TECHNOLOGY Avalon=1 1.05 1 0.9 1 1.3 1.3 1 1

This sets the basic technology ratings. As you can see, there is nothing really fancy here, just a slightly worse than normal cloaking device and some medium duty reactors.

&CLOAK Avalon=0 11 0 1 0 1

This sets up the cloak. It uses 11MW of power and it exists.

&BATT Avalon=0 0 1 2.75 1 &AUX Avalon=0 0 1 20 1 &MAIN Avalon=0 0 1 18.92 1 These are the reactors. Nothing particularly fancy here, if you don't know these variables... you're in too deep already.

```
&MOVEMENT Avalon=0 0 0 0 0.8 1000 0 0
```

This sets the movement ratios and the movement rating (?). The fifth variable is the one that adjusts the warp speed and the impulse speed. The movement rating is related to turning speeds, but that is really messy code, which doesn't need to be explained in too much depth here.

```
&SHIELD Avalon=4 14 1 1 0 0 0 0 1 1 1 1 8

&STRUCTURE Avalon=1 23020 2000 0 20 20 0 0 1 1 20 20
```

The final bit of the class... if you've looked at Mordak's crib sheet you'll understand the variables involved here.

6 – Save Yourself! (Some trouble)

An interesting title don't you think? That's because a lot of people have been asking the same questions over and over, and despite the question having been answered just as many times, people still ask them. This section is for answering them.

Q: When I adjust the settings on my ship (using SDB, the attributes, whatever) AttySpace doesn't see the changes.

A: This is because of one of a few things. You're trying to change the warp and impulse speeds with SDB... this isn't going to work, read the class section. Or... you're forgetting to sdb(read,<obj>) so that ASpace reloads the ship's statistics.

Q: My reactors don't work.

A: ENABLE TinyMath if you recompile.

Q: Ship A and Ship B have the same coordinates, but don't see each other on sensors.

A: Ensure that the space attribute on the ship objects is identical *and* make sure that they are both located in the same space room.

Q: I try some of the sdb() commands, but they don't seem to work on my ships.

A: Take a look at the sdb command table at the end of this document. Maybe you're calling the wrong command.

Q: How do I make a wormhole?

A: @create Wormhole 1

@create Wormhole 2

@parent Wormhole 1=#995

@parent Wormhole 2=#995

&STATUS Wormhole 1=0 0 0 0 0 0 0 0 0 <SDB of wormhole 2>

&STATUS Wormhole 2=0 0 0 0 0 0 0 0 0 <SDB of wormhole 1>

think sdb(read,<sdb of wormhole 1>)

think sdb(read,<sdb of wormhole 2>)

think sdb(put,<sdb of 1>,<value>,coords,x)

think sdb(put,<sdb of 1>,<value>,coords,y)

think sdb(put,<sdb of 1>,<value>,coords,z)

(etcetera)

If the object is in another space, any ship gating will be transferred to that space (ala the Alternate Universe on ATS, and the inside-wormhole-space).

(This is taken directly from Andy's post on the Aspace Forums)

Q: How do I change the territories?

A: The territories are hardcoded into the server. You have to edit space_variables.c to adjust the current ones and to add more you have to edit space.h. If you understand C the bits in those two files you have to edit are very straightforward. Important Note: In order to use the edited files you must recompile.

Q: Where can I get the help files from ATS?

A: You can't. Some people have logged ATS' help files in their entirety. Neither Mordak, Yarb nor myself endorses this activity, as technically it qualifies as copyright infringement.

Q: How do I recompile if I'm running Windows?

A: You can use either the freely available cygwin tools or the tools provided by Microsoft in Visual Studio 5 and higher. Do not ask for the VS tools, we can't provide them to you. However some of us are willing to use our resources to compile a custom server for you.

Q: My ships won't work... even if I follow the tutorial's instructions.

A: The tutorial forgot an important piece of information. Before you can sdb(read,#????) you have to set the ship object SPACE-OBJECT.

Q: The MUSH tells me that SHIP-OBJECT isn't a valid flag, you're wrong.

A: No, despite what you may think, I am not wrong. The original release of AttySpace, which this tutorial is based on, uses SHIP-OBJECT not SPACE-OBJECT. The flag was changed in more recent releases of ASpace.

Q: @zone isn't a valid command!

A: Again, this depends on the patch level of Penn you're using. If you're using an older version @zone is an alias for @chzone. (I use an older version of ASpace than what is present on the site.) Since some of you felt like complaining so much, all references to @zone are now redone to @chzone.

Q: Why don't my channels work? I'm using the ASpace site's win32 releases.

A: This is courtesy of some of the Penn features being disabled in those releases. You have three choices, live with it, recompile with those features enabled, or convince one of us who have experience recompiling to make a special compile for you.

Q: Are you that ASpace guy?

A: Quite obviously, it's nice that a lot of you use this tutorial, but if you're going to IM me asking if I'm the guy who wrote this tutorial... don't. Obviously if you're getting my IM information from the end of this document, you know that I'm the tutorial guy.

Q: Will Atty give me support for AttySpace or ASpace if I log onto ATS?

A: Definitely not. Atty released AttySpace without any support. If you log onto ATS and expect someone to help you with AttySpace coding you may find yourself booted. As stated in the disclaimer for ATS, they're happy that you want to emulate them, but ATS does not give away code. (AttySpace is an exception and the version released by Atty was an old version that doesn't have all the same features as the current version that ATS runs.)

Q: Didn't there used to be working hyperlinks in this tutorial?

A: Yes, there were. However I have had the interesting situation of several full system reinstalls and in the process misplaced my Adobe Acrobat CD, so as a temporary measure (that has become less than temporary) I'm using FreePDF and GhostView which unfortunately do not support many of the advanced PDF features.

Q: How do I... what is... how does...

A: Read over the older posts in the ASpace Support Forums. Chances are your question has been answered previously. If it's been brought up more than once and has a definite answer, you'll find it in here.

98 - Contact Information

There are several ways that you can contact me.

The first is email, I've recently changed my accounts a bit, so my primary email address is: damnal@the0rem.net. Older versions of the tutorial show cyberspeed@geocities.com as my primary account, please disregard this since Yahoo has recently changed their POP3 service and I only check that account on a random basis. Do not email my hotmail account. There is a 99% chance your message will not be received.

Another way of contacting me is through the Message Boards at http://aspace.whizy.com, however just like the email, it may take a day or two before I read your message.

My IM clients are now open much more than they had been before, so here's the communication info:

MSN Messenger: damnal@hotmail.com

ICQ: 34920675

AOL Instant Messenger: Damnal Sakotd

Yahoo! Instant Messenger: cyberspeed b@yahoo.com

99 - Change Log

12/21/02 – Added a few more questions to the Q&A section. Updated the note at the top since there has been a little confusion regarding my stockdb. Some minor grammar and spelling fixes throughout the tutorial. If anyone has any major issues I'll fix them when I get the chance. This tutorial has been helping people for two years?! Happy Holidays.

05/01/02 – Added a few new bits of info into the Save Yourself some trouble section. Updated the contact information to accurately reflect changes in my account info. All references to @zone have been changed to @chzone.

11/11/01 – Added an important piece of forgotten information to Section 1. I'm amazed no one mentioned that problem yet. Also fixed a few minor typos. Added the IM info to the end of the Contact Info since my OLT is much higher than it used to be.

11/04/01 – Added to Section 6. Covers territories and some other useful advice. Gave Yarb the credit for the work on the sdb() reference.

10/03/01 – Edited several mistakes. Added more contact info. Added a slightly modified version of Mordak's sdb() reference table to the end of the document for easier reference. More updates to save yourself some trouble.

07/11/01 – Section 6 added. Newest entry in changelog is now colorful. As are new section headings. (I'm bored). Added additional info before section 1, including a table of contents.

06/14/01 – Change Log renumbered to 99 (Contact info to 98) to prevent it from ever moving again. A few sections revised for wording and grammar. PDF releases start (I don't have the patience for multi-platform issues lately)

08/16/00 – Fixed parent # typo.

08/01/00 – Revised ship creation... forgot to upload newer document. Contact information added as section 6. Change Log moved to 7.

06/03/00 – Fixed a lot of typos. Change Log moved to Section 6, Section 5 created.

05/16/00 – First copy, basic coverage of creating ships.

05/22/00 – Updated information within section 2

05/23/00 – Updated section 2, 3, and 4.
